

Caution

When the hour angle approaches 90° , a significant error of 1 or 2 miles, may occur when computing the altitude of celestial bodies.

It is a good plan to discard those sights, where the value of "K" is found to lie between the limits of $87^\circ 30'$ and $92^\circ 30'$.

**Dead Reckoning
Altitude and Azimuth Tables**

Preface

This table was conceived, and the method and formula deduced, by Lieut. Arthur A. Ageton, United States Navy, while a member of the Line Class of the Postgraduate School, United States Naval Academy, Annapolis, Md.

Acknowledgment is made for helpful suggestions and constructive criticisms submitted by members of the staff of the Postgraduate School, members of the Line Class of the Postgraduate School and other officers of the Navy.

First published in 1931 by the U.S.Navy Hydrographic Office but discontinued as a separate publication in 1972 by the successor, the Defense Mapping Agency Hydrographic/Topographic Center and republished in 1975 by the same agency as table 35 of *Volume II: The American Practical Navigator* but is no longer included. Popularly known as the AGETON method.

The table is based on a divided triangle method in which a perpendicular is dropped from the geographic position (GP) of the body to the meridian of the observer.

The distinctive features of this method of navigation are:

1. The dead reckoning (D.R.) position of the ship is used for working sights and plotting lines of position.
2. There is no *interpolation* for practical navigation.
3. The azimuths can be most positively determined.
4. the solution is short, simple, and *uniform* under all conditions.

In spite of the several other short methods devised in recent years, there are still many navigators who prefer to work from their D.R. position. As the navigator's work at sea consists largely of computing lines of position, this table has been arranged primarily for computation of altitudes and azimuths from the D.R. position.

The time and labour required to work a sight from the D.R. position have been materially reduced. In point of time, this method compares favourably with the various short methods.

The method of solving navigational problems here given is applicable to all problems regardless of the position of the heavenly body, be it sun, moon, planet or star or latitude of the navigator. It requires few figures and gives quick solution for determining a line of position (LOP). The table is simple to use and offers, in conjunction with the Nautical Almanac, an alternative sight reduction method to, e.g. U.S. Pub. 229, U.S. Pub. 249 or NP303 (AP 3270) and as no navigator should ever become completely dependent on electronic navigation methods, a viable compact back-up method to these methods.

Problem IV - the latitude by Phi Prime, Phi Second - and figures 1 and 2 have been reproduced from "Primer of Celestial Navigation" by John Favill, M.D.

Every effort has been made to make this table error-free.

W. C. S.
2011

Method of Solution

The work form shown may be used for sun, moon, star and planet.

Typical solutions for the sun and a star are shown. The following steps are taken to obtain the altitude and azimuth in one combined solution.

1. Find the Greenwich hour angle (GHA) in degrees and minutes.
2. Apply to the GHA the D.R. longitude (Long D.R.) to obtain to the nearest tenth of a minute the local hour angle (LHA) east or west of the local meridian from 0° to 180° .
3. Enter on form declination (d) and D.R. latitude (Lat D.R.) to nearest tenth of a minute and name them N or S.
4. Correct Hs (sextant altitude) to obtain Ho (observed sextant altitude) to the nearest tenth of a minute.
5. The letters **A** and **B** on the form *merely indicate from which column to take their corresponding functions.*
6. Enter table with LHA and take from **A** column the nearest tabulated number. Enter table with declination and take tabulated number from **B** column. *Add* these numbers. For practical navigation do not interpolate*.
7. Look up the number thus obtained in **A** column and take from the **B** column the opposite tabulated number. *Subtract* this from the function of declination taken from the **A** column.
8. Enter **A** column with the number thus obtained and take out nearest tabulated value of **K**, the degrees from the top or bottom of the page and the minutes from the side.
- 9. Give K the same name as declination. Combine K with latitude to obtain (K~L), adding K and latitude if different names and subtracting the smaller from the larger if same name.**
10. Enter table with (K~L) and take from the **B** column the nearest tabulated number. *Add* this to the **B** function of **R** as shown on the form.
11. With the number thus obtained, enter the **A** column and take Hc (calculated sextant altitude) from the table.
12. The difference between the computed altitude (Hc) and the observed altitude (Ho) is the altitude difference or altitude intercept abbreviated (a); "a" is measured from the D.R. position toward the body when Ho is greater than Hc, and away when smaller. The line of position is plotted from the D.R. position.
13. To compute the azimuth, look up Hc in the **B** column and *subtract* the number thus obtained from the **A** function of **R** which has already been determined.
14. With this number, enter the **A** column and take out **Z** to nearest minute. **Z** is always measured from the elevated pole (latitude) 0° to 180° east or west to the body.

At the top of the pages of the table are stated the only two rules required.

In **PROBLEM I**, LHA is less than 90° and **K** is taken from the top of the table.

When LHA is greater than 90° , **K** should be greater than 90° . In **PROBLEM II**, LHA is greater than 90° and **K** is therefore taken from the bottom of the table., which automatically converts **K** into the proper angle greater than 90° .

PROBLEM I illustrates the delicacy with which the azimuth may be determined even when the body is very near the prime vertical. **K** is a little less than the latitude and the same name. According to the azimuth rule, **Z** is taken from the bottom of the table.

PROBLEM II illustrates the case when **K** is the same name as and greater than the latitude, and **Z** is accordingly taken from the top of the table.

When **K** and latitude are different names, **Z** is taken from the bottom of the table.

ACCURACY

* This table gives an accuracy of solution to within five-tenths of a minute in altitude and an average error of only two-tenths of a minute without interpolation. The navigator who wishes greater accuracy should interpolate between tabulated functions.

If considered desirable, the possible error in Hc may be reduced to two-tenths of a minute by interpolating when taking Hc from the table.

SHORTCUTS

Certain shortcuts will become apparent with use of the table:

When entering the table with declination, take function from both **A** and **B** columns in one entry.

When taking Hc from the table, take the tabulated function from the **B** column at the same time, as it will be used in computing **Z**.

Line of Position Examples

For the sake of brevity the corrected observed altitude (Ho) will be given in each case instead of the sextant altitude (Hs).

PROBLEM I: At 7:31 AM on December 31 ship was in D.R. position, latitude $42^{\circ} 10' 30''$ S, longitude $68^{\circ} 37' 42''$ W.

Sun was observed on the prime vertical at (GMT)UT 12:31:16. Corrected observed altitude (Ho) is $35^{\circ} 57.0'$.

*LHA measured eastward or westward from the observer's meridian (Long D.R.) to the observed body's hour circle (GHA).

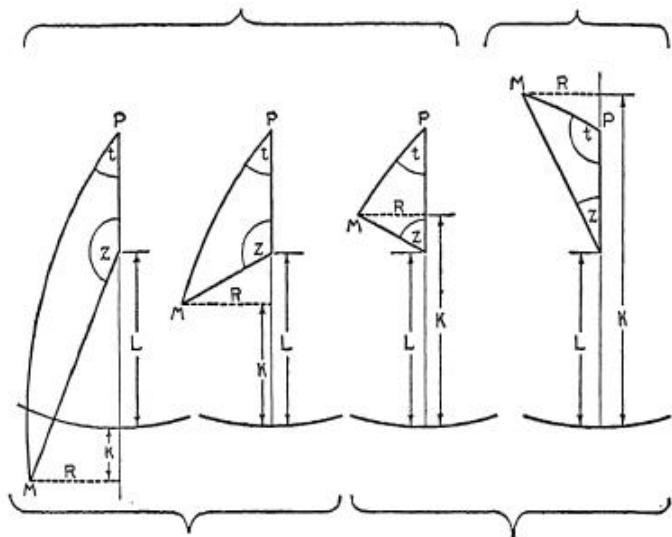

Note 1: Give "K" same name as declination (d) N or S and take from bottom of table if LHA (E or W) is greater than 90° .

Note 2: Combine LHA (E or W) and "K", adding when different names and subtracting when names are same.

Note 3: Always take "Z" from bottom of table, except when "K" is same name and greater than latitude, in which case take "Z" from top of table. Give "Z" prefix same name as elevated pole (Lat D.R.) and suffix same name as LHA (E or W).

"Z" is the azimuth measured from the elevated pole position (Lat D.R.) east or west through 180° . "Zn" is the azimuth measured from the north point clockwise through 360° and rounded to the nearest whole degree.

Rule 1: K is always $< 90^\circ$
 Take K from top of table } except when $\begin{cases} t \text{ is } > 90^\circ \\ \text{Take } K \text{ from bottom of table} \end{cases}$

Rule 2: Z is always $> 90^\circ$
 Take Z from bottom of table } except when $\begin{cases} K \text{ is same name as } & > \text{ latitude} \\ \text{Take } Z \text{ from top of table} \end{cases}$

Of course, if $\begin{cases} K = L \text{ then } Z = 90^\circ \\ t = 90^\circ \text{ then } K = 90^\circ \\ K \text{ takes same name as declination (N. or S.)} \end{cases}$

Fig. 1

Development of the Formulas

The spherical triangles used in navigation are shown projected on the plane of the horizon in above figures

The parts of the triangle are lettered as follows:

P. Pole

Z. Zenith of observer. The azimuth (angle PMZ) is also called Z.

M. Heavenly body observed.

L. Latitude of the observer.

d. Declination of body M.

t. (or LHA). Local hour angle of body M.

H. Altitude of body M.

R. Perpendicular let fall from M on PZ. This is an auxiliary part.

X. Intersection of R with PZ.

K. Arc from X to the equinoctial. This is an auxiliary part introduced to facilitate solution.

The following formulas have been derived:

From triangle PMX - 1. $\csc R = \csc t \sec d$ 2. $\csc K = \csc d / \sec R$

From triangle ZMX - 3. $\csc Hc = \sec R \sec (K-L)$ 4. $\csc Z = \csc R / \sec Hc$

In right triangle PMX, t and d are known. R may be found from formula (1). Knowing R and d, K may be found by formula (2). K is then combined algebraically with L to obtain (K-L).

In triangle ZMX, the sides R and (K-L) are known. Hc may be found by formula (3). the azimuth Z, is computed by formula (4).

All formulas are in terms of secants and cosecants. The table is arranged in parallel "A" and "B" columns, the "A" columns containing the log cosecants multiplied by 100,000 and the "B" columns log secants multiplied by 100,000. This device has greatly simplified the arithmetic solution. The tabulation of functions every half of a minute throughout the table has helped *interpolation*.

RULE 1: When LHA (E or W) is greater than 90°, take "K" from bottom of table

APPENDIX A

Latitude by Phi Prime, Phi Second (Favill)

PROBLEM IV: At anchor, in evening of August 21, in latitude $42^{\circ} 12' N$, longitude $87^{\circ} 48' W$, observed star Deneb, bearing ENE, as follows:
sextant altitude (Ho) $58^{\circ} 52'$, at Universal Time ((GMT)UT) 1:39:20 AM August 22.

	h m s			
(GMT)UT	01 : 39 : 20 (Aug. 22)			
GHA	44 - 27.4 (W)			
Long	87 - 48.0 W	Add	Subtract	Subtract
LHA	43 - 20.6 E	A 16346		
d	45 - 03.1 N	B 15089	A 15014	
Ho				A 6754
R		A 31435	B 5822	B 5822
\emptyset''	54 - 01.5 N	<-----	A 9192	
\emptyset'	11 - 49.5 N	<-----	B 932	
Lat	42° 12' N			

Old method for determining latitude from (a) a single altitude of a body not on the meridian, (b) UT of the observation and (c) known longitude but is now seldom used. The method is best restricted to conditions where the body is within 3 hours (45 degrees) of meridian passage, of declination at least 3° and not over 45° from the meridian in azimuth. This last means that a line from the body to zenith should not make an angle of over 45° with meridian. (see Fig. 2)

Projection of the Celestial Sphere on the Plane of the Horizon.

$WQE =$ Equator	$h =$ Altitude
$Z =$ Zenith	$Mm =$ Perpendicular from Body to
$P =$ Elevated Pole	Meridian = l
$M =$ Body	$\phi' = mZ =$ Zenith distance of m
$d =$ Declination	$\phi'' = mQ =$ Declination of m
	$QZ =$ Latitude to be found

NOTE:

Give \emptyset'' same name as declination

\emptyset' is N if body bears N & E or N & W

\emptyset' is S if body bears S & E or S & W

Combine by adding if different, subtracting if alike

Lat = $\emptyset' \pm (180^{\circ} - \emptyset'')$ for lower transit

Fig. 2

Reduction to the Meridian

To use H.O. 211 for reduction to the meridian, two conditions must be fulfilled.

1. The LHA must be less than 20 minutes time (5° arc)
2. The angular distance between the sun and the zenith of the DR position ($L-d$) must be greater than 15° arc.

The following formulas are used:

$$1. \csc R = \csc t \sec d \quad 2. \csc K = \csc d / \sec R \quad 3. \sec(K-L) = \csc Ho / \sec R$$

Knowing the D.R. latitude, K and $(K-L)$ may be combined to give the latitude at the time of the sight. It will be noted that the first two formulas are the same as those used in computing the altitude and that the third is the reverse of the third altitude formula.

PROBLEM V: An altitude of the sun was taken near Local Apparent Noon (LAN) and the following data obtained: Local Hour Angle (LHA) $2^{\circ} 30' E$, declination (d) $3^{\circ} 45' S$, DR latitude (L) $21^{\circ} 06' S$, sextant altitude (Ho) $72^{\circ} 31.1'$.

	Add	Subtract		Subtract
LHA	2 - 30.0 E	A 136032		
d	3 - 45.0 S	B 93.1	A 118440	Ho 72 - 31.1
R	A 136125.1	B 41.1	A 2054
K	3 - 45.0 S	<-----	A 118398.9	B 41.1
$(K-L)$	17 - 18.5	<-----	B 2012.9	
L	21 - 03.5 S (at time of sight)			

As long as LHA is less than 5° and $(L-d)$ is greater than 15° , the error will not usually be greater than $0.5'$ of latitude. Occasionally the $0.4'$ possible error of the table and the $0.5'$ possible error of this approximation may combine to produce a maximum error of $0.9'$ in latitude.

When conditions do not conform to the requirements of this method, compute the altitude and the azimuth in the usual manner and plot the line of position on the chart.

NOTES
